

engineering case study

estimated duration: 1–3 hours

tech stack: any js/ts/ruby/python stack + postgresql/mysql/mongodb

objective: build a simple web app that fetches real-time news articles, uses AI to generate a summary and sentiment analysis, and stores the results in a db

AI: using AI coding tools is encouraged. however, the next step will be a no-AI live coding session in this codebase. keep this in mind when choosing the tech stack

overview

you are tasked with building a web app that allows users to:

1. search for recent news articles using a public API
2. select an article and trigger:
 - a summary using openai API
 - a sentiment score (i.e. positive/neutral/negative)
3. store the results in a db
4. display all results and their analysis to the user

how the user selects, requests or does not select an article is up to you to design. but the app should be useful and not arbitrary

what to focus on

- product design and UX
 - REST API design
 - AI features
-

APIs you'll use

1. news API

i.e. <https://gnews.io> (free tier: 100 requests/day)

(or any news/RSS feed you care about)

2. openai API

you will be provided with an openai API key with access to `gpt-4.1-nano`. you won't be judged on model selection or generation quality

infrastructure

please host the app anywhere you want. here're some great free options:

- <https://vercel.com>
- <https://railway.com>
- <https://render.com>

no need to worry about it being accessible to everyone

handover

once you have completed the task, please reply with the following:

- github repo link. public or private. if it's private, invite these 2 gentlemen: <https://github.com/nicholas-greenwood>, <https://github.com/mohammad-chaudry>
 - live app link
 - optionally - a short walkthrough video
-

good luck!

we're excited to see how you approach the problem, balance architecture, and execute cleanly under a short time constraint

please reach out to nicholas@aries.global if you have any questions
